

NBA win probability tech task

The following task should take 2-3 hours. Code, in the language of your choice, and a brief summary should be sent to your recruiter at least 24 hours before your subsequent interview. A link to a Github repository is ideal. Be prepared to discuss, screen share, and run your model during the interview.

The dataset `nba-win-probability-data.csv` contains 1,230 observations of NBA games in the 2025-26 season. There are fourteen columns, which are defined as follows:

- `game_id`: A unique identifier for each game.
- `game_date`: The date the game took place.
- For each team there are seven columns:
 - `away/home`: A three-letter team identifier.
 - `away/home_wins`: The number of games the team won in the season prior to the game.
 - `away/home_losses`: The number of games the team lost in the season prior to the game.
 - `away/home_points`: Total team points.
 - `away/home_turnovers`: Total team turnovers.
 - `away/home_fouls`: Total team fouls.
 - `away/home_rebounds`: Total team rebounds.

Use the game data from October through March to train, validate, and test a model that gives the home team win probability for April games.

Contact your recruiter if you have any questions.
